(54) **Thickening agent which modifies the rheological characteristics of charged and/or pigmented, white or colored aqueous compositions**

(57) Associative thickening copolymer water-soluble in a neutral or alkaline medium, for charged and/or pigmented, white or colored aqueous compositions, composed

- a) of at least one ethylenically unsaturated monomer having at least one carboxylic function,
- b) of at least one other ethylenically unsaturated monomer devoid of carboxylic function.
- c) of at least one surfactant monomer having at least one urethane function resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound, having a hydroxyl function that is reactive towards the $-NCO$ group,

characterized in that said copolymer belongs to the group consisting of those which, by definition, when placed in an aqueous solution containing 2 % by weight of dry matter and brought to pH 9 by the addition of ammonia, at a temperature of 20 °C, have a Brookfield viscosity at 100 rpm of at most equal to 220 centipoises.

The copolymer according to the invention is used in charged and/or pigmented aqueous compositions such as coating compositions, and more particularly in paints, coating slips, printing pastes, leather finishing products, compositions for cosmetics and detergents, and drilling fluids.

Description

Thickening agent which modifies the rheological characteristics of charged and/or pigmented, white or colored aqueous compositions

Field of the invention

The invention relates to an associative thickening copolymer that is water-soluble in a neutral or alkaline medium, and has the property of modifying the rheological characteristics of charged and/or pigmented, white or colored aqueous compositions.

The invention also relates to charged and/or pigmented, white or colored aqueous compositions for which it is desirable that they have a Newtonian behavior and which contain said associative thickening copolymer whose effect on the medium simultaneously provides a good rheological compromise at high and low shearing stress, which is reflected by good covering and film tension characteristics after application, while retaining good resistance to running.

In the description of the subject of the invention, the expression "charged and/or pigmented, white or colored aqueous compositions" defines the field of aqueous compositions of charges and/or pigments such as coating compositions and, more particularly, paints, coating slips, printing pastes, leather finishing products, compositions for cosmetics and detergents, and drilling fluids.

Moreover, and more particularly in the case of paints, "covering power" characterizes the quantity of paint deposited per unit surface area, "resistance to running" defines the ability of a paint to resist running after its application to a substrate to be protected. and

finally “film tension” after application defines the ability of said paint to even out the thickness irregularities resulting from its application on a substrate to be protected.

Background of the invention

For a person skilled in the art, a charged and/or pigmented aqueous composition is formed from a liquid phase which may be water or an organic water-miscible solvent, or even a mixture of these two, from a polymer in emulsion in the liquid phase which is called “binder”, from charges and/or pigments, from an agent which disperses the charges and/or pigments which can be a water-soluble polymer or copolymer, from adjuvants as varied as coalescence agents, biocides, antifoaming agents or others, and finally from a thickening agent which is a natural or synthetic polymer or copolymer.

For a long time it was found during use that the presence of a thickening agent in a charged and/or pigmented aqueous composition was necessary in order to modify its rheological characteristics.

Several species of thickening agents for charged and/or pigmented aqueous compositions have already been proposed to persons skilled in the art and have been abundantly described in the specialized literature.

A first species of thickening agents for charged and/or pigmented aqueous compositions consists of cellulose derivatives which have the property of viscosifying only the aqueous phase of said compositions.

However, the field of application of this first species of thickening agents is a limited one, because disadvantages occur, causing problems to the user, disadvantages such as difficulties of dissolution in the aqueous media, an often slow hydration kinetics, high sensitivity to bacteria, and also an inability to develop, and more specifically, to adjust *a posteriori*, the viscosity of the charged and/or pigmented aqueous compositions.

Thus it seems that this first species of thickening agents causes, within charged and/or pigmented aqueous compositions in which it is used, pseudo-plastic rheological characteristics which could be troublesome, such as a high viscosity in the absence of mechanical stress but which decreases to a very great extent under the effect of shearing stress, resulting in a poor covering power.

Another species of thickening agents has been proposed for overcoming the aforementioned drawbacks of this first species. This other species is formed from synthetic latexes which may be acrylic, illustrative descriptions of which are given e. g. in patents such as French Patent 2,131,128, French Patent 2,281, 389. U. S. Patent 2,798,053, U. S. Patent 2,985,625 or even U. S. Patent 2,958,679.

Thus, a description is given (French Patent 2,281,389) of a cross-linked polymer of maleic anhydride and ethylene in the presence of trialkyl isocyanurate, which can be used as thickening agent for aqueous systems such as synthetic latex-based paints, for the flocculation treatment of ores, and for coagulation treatment of industrial or domestic water.

These thickening agents are generally polymers of carboxylic acids having an ethylenic function, or copolymers of these same acids and their esters present in the form a low-viscosity aqueous emulsion of the oil in water type.

These thickening agents, which are soluble in aqueous and alkaline media, have the advantage over the above-mentioned cellulose derivatives of being more easily used and of being insensitive to bacterial attack.

However, as the first species of thickening agents, the second species has certain drawbacks such as causing the thickening of only the aqueous phase of said compositions, or even of providing these compositions with highly pseudo-plastic rheological characteristics which are not suitable for all paint formulations.

More recently a last species of water-soluble thickening agents has appeared in the field of charged and/or pigmented aqueous compositions, thickening agents traditionally called associative thickening agents, because they act not only by increasing the viscosity of the aqueous phase (by solubilization) but also by creating various bonds between the copolymer and certain constituents of the compositions, most likely through the appearance of hydrophobic interactions and hydrogen bonds. The advantage of these associative thickening agents over the aforementioned agents is to provide the charged and/or pigmented compositions in which they are used with a less pseudo-plastic behavior.

In particular, in the case of certain paints, a person skilled in the art seeks to obtain a viscosity under low shear stress which is sufficiently low so that the film deposited on the substrate to be protected has a tendency to level out well the thickness irregularities caused by the application (appropriate film tension), and has a viscosity under high shear which is sufficiently high for improving the covering power and for decreasing the projections when said paints are applied by means of a roller.

This last species of associative thickening agents has developed into two families, that of polyurethane associative thickening agents and that of acrylic associative thickening agents.

The polyurethane associative thickening agents which belong to the first family possess, in their molecule, one or more polyether chains terminating with hydrophobic groups such as e.g. alkyls, aryls, alkylaryls, and are obtained by condensation chemistry.

Such agents are described in many patents, e. g. in British Patent 1,069,735, U. S. Patent 3,770,684, U. S. Patent 4,079,028 and U. S. Patent 4,155,892.

But, although these agents provide the charged and/or pigmented compositions in which they are used with desirable rheological characteristics, they are the source of certain troublesome disadvantages for their user.

In effect, these agents are present in a viscous form which is not easy to handle, possibly in solution in mixtures of water and solvent(s), and the solvent may be more or less toxic and thus these agents may be of limited use, or even have reactive incompatibilities with certain constituents of the charged and/or pigmented compositions.

The acrylic associative thickening agents obtained by radical polymerization, belonging to the second family and water-soluble in a neutral or alkaline medium, are formed from copolymers generally prepared from ethylenic carboxylic acids, possibly of esters of these acids and/or other monomers, and finally from at least one particular functional monomer having a side chain composed of polyether groups possessing hydrophobic hydrocarbon terminal groups.

The nature of the particular functional monomer has been found to be a determining factor in the rheological behavior of the charged and/or pigmented compositions containing the corresponding thickening agent.

Thus, the particular functional monomer may be an acrylate or methacrylate of a surfactant alcohol (European Patent 0 013 836 and U. S. Patent 4,384,096) or it may result from the esterification by a surfactant alcohol of acrylic acid oligomers (U. S. Patent 4,421,902). This particular functional polymer may also be an oxyethylated ester of crotonic acid (U. S. Patent 4,569,965) or even a half ester of maleic anhydride (European Patent 0 248 612) or a surfactant ether of allyl alcohol (European Patent 0 216 479).

Finally, this particular functional monomer can result from the condensation of a surfactant alcohol and an unsaturated isocyanate (U. S. Patents 4,514,552 and 4,600,761), the presence of O-C(O)-NH- urethane groups on the side chains of the copolymer producing a beneficial effect on the rheological behavior of the charged and/or pigmented aqueous compositions and particularly of the aqueous paints.

The object sought by the use of the acrylic associative thickening agents was to modify, in the most favorable manner, the rheological characteristics of said compositions by their presence, so that they preferably have a controlled viscosity simultaneously under high and low shearing stresses, so as to have a good covering power, an acceptable resistance to running and an appropriate film tension.

Now, it has been noted that among the many prior-art associative acrylic thickening agents

- some already had an acceptable rheological profile, but at the price of high amounts of use which the formulator wanted to see decreased,
- others, such as those mentioned in U. S. Patent 4,514,552, did not manage to control simultaneously the viscosities at high and low shearing stresses..

Summary of the invention

In view of the aforementioned drawbacks, the Applicant, in carrying out his studies, has found and perfected an associative thickening copolymer which is water-soluble in a neutral or alkaline medium and, unlike the prior art, provides the charged and/or pigmented aqueous compositions with a good state of rheological compromise at high and low shearing stresses which is reflected by a high covering power and a good film tension while retaining an excellent resistance to running, both for white and colored compositions, and which uses lower quantities.

According to the invention the associative thickening copolymer water-soluble in a neutral or alkaline medium and composed

- a) of at least one ethylenically unsaturated monomer having at least one carboxylic function,
- b) of at least one other ethylenically unsaturated monomer devoid of carboxylic function.
- c) of at least one surfactant monomer having at least one urethane function resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound, having a hydroxyl function that is reactive towards the -NCO group,

is characterized in that said copolymer belongs to the group consisting of those which, by definition, when placed in an aqueous solution containing 2 % by weight of dry matter and brought to pH 9 by the addition of ammonia, at a temperature of 20 °C, have a Brookfield RVT viscosity at 100 rpm of at most equal to 220 centipoises.

Detailed description

The associative thickening copolymer according to the invention is distinguished from the prior art in that it provides a state of compromise in said compositions and paints, leading to a balance between the extreme effects previously observed.

In other words, the associative thickening copolymer of the invention, when used in charged and/or pigmented aqueous compositions, generates media whose general rheological characteristics approach a Newtonian behavior, media whose viscosity under high shearing stress is increased and whose viscosity under low shearing stress is decreased in relation to the prior art, thereby improving the covering power and film tension characteristics after application, while maintaining a good resistance to running,

The Newtonian behavior of the aqueous compositions containing the associative thickening copolymer according to the invention is acquired jointly as a result of the

incorporation, in its structure, of a surfactant monomer having at least one urethane function, and the fact that the molecular weight of said copolymer is very low, said molecular weight being expressed by measurement of the mobile 1 to 3 RVT Brookfield viscosity at 100 rpm of an aqueous solution containing 2 % by weight of said dry copolymer brought to a pH of 9 by the addition of ammonia and at a temperature of 20 °C, the upper limit of the Brookfield viscosity measured under these conditions being 220 centipoises at the most.

•

Apart from this conditional field of Brookfield viscosities as indicated above, any copolymer of the same structure but generating a viscosity of more than 220 centipoises under the conditions indicated for this measurement leads to aqueous compositions having perturbed, even bad, rheological characteristics when used as a thickening agent, more precisely in the case of gloss or semigloss paints.

Thus, as Applicant was able to note, it appeared in a surprising manner that the two above-mentioned conditions leading to the copolymer according to the invention fully cooperate, by the selection of low molecular weights, in creating a state of synergy which makes it possible to obtain charged and/or pigmented, white or colored aqueous compositions having rheological characteristics which approach a Newtonian behavior.

The associative thickening copolymer according to the invention is composed, as already stated above, of at least three types of monomers.

The first type of monomer, which is an ethylenically unsaturated carboxylic acid, is a compound having an ethylenic bond and at least one carboxyl group or a carboxylic acid anhydride group.

The carboxylated ethylenic monomer may be selected from among monoacids, such as acrylic acid, methacrylic acid, crotonic acid, isocrotonic acid, cinnamic acid; diacids such as itaconic acid, fumaric acid, maleic acid, citraconic acid; anhydrides of carboxylic

acids such as maleic anhydride; and half esters of diacids such as the C₁ to C₄ monoesters of maleic acid or itaconic acid.

However, the carboxylated ethylenic monomer is preferably selected from the group consisting of acrylic acid, methacrylic acid and itaconic acid.

The second type of monomer, devoid of carboxylic function and which is ethylenically unsaturated, may be selected in a nonlimitative manner from the group comprising acrylic acid esters or methacrylic acid esters such as methyl, ethyl, butyl, 2-ethylhexyl, lauryl acrylates or methacrylates, acrylates and methacrylates of ethylene glycol, propylene glycol, polyethylene glycol and polypropylene glycol, as well as corresponding phosphates and sulfates; acrylonitrile, acrylamide, N-methylolacrylamide, dimethylaminoethyl acrylates and methacrylates, allyl alcohol, vinyl acetate, acrylamidomethyl-propanesulfonic acid, styrene and methylstyrene.

However, the second type of ethylenically unsaturated monomer is preferably selected from among acrylates, such as C₁-C₄-alkyl acrylates and methacrylates.

The third type of monomer, which is a surfactant monomer having at least one urethane function, results from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound having a hydroxyl function that is reactive with regard to the -NCO group.

The ethylenically unsaturated isocyanate can be prepared by methods well known to persons skilled in the art, methods such as those described e. g. in U. S. Patent 2,718,516.

However, since these methods of preparation of ethylenically unsaturated isocyanates are relatively long, it is often preferable to use known ethylenically unsaturated monoisocyanates such as e. g. isocyanatoethyl methacrylate (sold by DOW CHEMICAL

COMPANY), or the meta or para isomers of α , α -dimethylisopropylbenzyl isocyanate (sold by AMERICAN CYANAMID CORPORATION).

However, a preferred method of preparation consists in dropwise stoichiometric addition, to a diisocyanate, of an ethylenic compound having a single hydrogen that is active with regard to the -NCO groups under the reaction conditions chosen.

For the ethylenic compound it is possible to use, for example, acrylates and methacrylates of ethylene glycol, propylene glycol, polyethylene glycol and polypropylene glycol, allyl alcohol, allylamine, methallylamine and o-allylphenol.

For the diisocyanate, it is possible to use, for example, 1,4-tetramethylene diisocyanate, 1,6-hexamethylene diisocyanate, 2,2,4-trimethyl-1,6-diisocyanatohexane, 1,10-decamethylene diisocyanate, 4,4-methylene-bis-(isocyanatocyclohexane), 1,4-cyclohexylene diisocyanate, 1-isocyanato-3-isocyanatomethyl-3,5,5-trimethylcyclohexane, m- and p-phenylene diisocyanate, 2,4- and 2,6-toluene diisocyanate, xylene diisocyanate, 4-chloro-1,3-phenylene diisocyanate, 4,4'-methylene diphenylisocyanate, 1,5-naphthalene diisocyanate, or tetrahydronaphthalene diisocyanate.

The surfactant compound having a hydroxyl function reactive with regard to the -NCO group of the ethylenically unsaturated isocyanate has the general formula:

wherein

- the term (O-R₂) is ethylene oxide, propylene oxide, butylene oxide or a combination of at least two of these oxygen-containing groups;
- n, which represents the average number of terms present in said surfactant, has a value of between 5 and 150;
- the term R₁ is selected from the group consisting of hydrocarbon and/or amine chemical structures, such as aliphatic or cycloaliphatic alkyls, substituted or

unsubstituted aryls, polyaryls having 1 to 32 carbon atoms, secondary amines of formula $(R_3)(R_4)N-$, in which R_3 and R_4 are hydrocarbon groups having 1 to 20 carbon atoms.

Thus, the surfactant compound provided with a hydroxyl function that is reactive with regard to the $-NCO$ group may preferably be selected from ethoxylated dilaurylamines, ethoxylated octyl and nonyl phenols, ethoxylated lauric, stearic, cetyl alcohols, ethoxylated mono-, di- and tristeryl phenols, taken alone or in a mixture.

Preferably, the term R_1 is selected from among the C_{12} to C_{30} hydrocarbon chains, the term $-O-R_2$ from the ethylene and/or propylene oxides, and n in the range of 15 to 50.

The associative thickening copolymer according to the invention contains, expressed in terms of percent by weight:

- a) from 15 to 75 % and preferably 30 to 45 % of other ethylenically unsaturated monomer(s) having at least one carboxyl function;
- b) from 25 to 70 %, preferably 45 to 60 % of other ethylenically unsaturated surfactant monomer(s) devoid of carboxyl function,
- c) from 0.5 to 35 %, preferably 4 to 15 % of surfactant monomer(s) having at least one urethane function resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound having at least one function that is reactive with regard to the $-NCO$ group, the total of components (a), (b) and (c) being equal to 100.

The associative thickening copolymer according to the invention, i. e. that having a Brookfield viscosity at 100 rpm of at most equal to 220 centipoise under the above-mentioned conditions is prepared by known radical copolymerization processes, in solution, in emulsion or in suspension, of the mixture of the above-mentioned monomers, in the presence of a catalytic system and of known transfer agents used in appropriate amounts, the molecular weight of said copolymer being adjusted by the

following means: temperature, amount of catalyst, presence of a transfer agent or any other means or combination of means known to persons skilled in the art.

The catalytic system of polymerization is desirably selected from among those that are water-soluble, such as sodium persulfates, potassium persulfates, ammonium persulfates, used in combination with a known reducing compound such as sodium metabisulfite.

The amount of catalytic system of polymerization can vary between 0.1 % and 2 % by weight of the total weight of monomers used for obtaining the copolymer according to the invention.

The transfer agent is desirably selected from among the alkyl mercaptans such as octanethiol, decanethiol, n-dodecanethiol and tert.-dodecanethiol.

The amount of transfer agent can vary between 0 % and 5.0 % by weight relative to the total weight of the monomers present.

The copolymerization temperature can vary between 30 °C and 150 °C. It is preferably selected to be lower than the lowest boiling point of the components present under the experimental conditions.

The copolymers according to the invention develop their thickening property in an alkaline medium, in such a way that the carboxyl functions present are totally or partially neutralized, the neutralization agent preferably being lithium hydroxide, sodium hydroxide, potassium hydroxide, ammonium hydroxide, calcium hydroxide, magnesium hydroxide, an amine, or a combination of these agents.

The invention also relates to charged and/or pigmented aqueous compositions containing the copolymer according to the invention.

The charged and/or pigmented aqueous compositions are more particularly

those which, white or colored, contain, as principal constituents, an aqueous phase, charges and/or pigments, a natural or synthetic binder, and possibly, as secondary constituents, a dispersing agent, adjuvants as diverse as coalescence agents, biocides, surfactants, antifoaming agents or others, and the associative thickening copolymer according to the invention.

The associative thickening copolymer according to the invention is introduced into said compositions in an amount of 0.1 to 10 %, preferably 0.1 to 5.0 %, and quite preferably 0.4 to 1.5 %, calculated in percent by dry weight based on the total weight of the composition.

In practice, the liquid phase resulting from the copolymerization can be used in that form as associative thickening agent, but it can also be dried by any method known for eliminating this phase and isolate the copolymer in the form of a fine powder and used in this other form as associative thickening agent.

The associative thickening copolymer according to the invention is used in charged and/or pigmented aqueous compositions such as coating compositions, and more particularly paints, coating slips, printing pastes, leather finishing products, compositions for cosmetics and detergents, and drilling fluids.

The scope and importance of the invention will be better understood by means of the following examples.

Example 1

The object of this example is to illustrate the preparation of a surfactant monomer resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound having a hydroxyl function that is reactive with regard to the -NCO group.

To this end, the surfactant monomer was prepared in accordance with the following reaction scheme:

Etape 1 ①

Etape 2

Tol : C₆H₃-CH₃

Ph : C₆H₄

Glossary: 1 – Step 1; 2 - ethylenically unsaturated isocyanate; 3 - monomer M2

- (1) : Source of ethylenic unsaturation
- (2) : Diisocyanate
- (3) : Ethylenically unsaturated isocyanate
- (4) : Surfactant compound (alcohol)
- (5) : Ethylenically unsaturated surfactant monomer

wherein (3), the ethylenically unsaturated isocyanate, reacts with (4), which is the surfactant compound.

The preparation was carried out according to the following steps:

In a reactor equipped with a mechanical stirrer and a Dean-Stark separator surmounted by a reflux condenser were placed 154 grams of nonylphenol poly(ethyleneoxy)₂₉ ethanol and 200 grams of heptane. The mixture was then heated to 90 °C to dehydrate the surfactant. When the amount of water collected in the separator no longer changed, the heptane was distilled first at atmospheric pressure and then under reduced pressure (5 mm Hg). The mixture was then cooled, then maintained at the melting temperature of the surfactant.

17.4 grams of toluene diisocyanate, 3 drops of alloocimene (polymerization inhibitor) and 0.24 gram of dibutyltin dilaurate (catalyst) were placed in a beaker. The beaker was placed in a water-ice bath and magnetically stirred at 50 rpm.

5.8 grams of allyl alcohol kept on a molecular sieve is placed in a dropping funnel. The allyl alcohol was dropwise added in 30 minutes to the toluene diisocyanate, in such a way that the temperature of the reaction medium does not exceed 20 °C. The medium was then stirred until determination of the NCO groups indicates that 50 % of the isocyanate functions has reacted. The content of the beaker was then poured in the reactor containing the molten surfactant alcohol. The medium was then left under stirring for 2 hours. Determination of the NCO groups then showed that all the isocyanate functions initially present had disappeared. In this manner a surfactant monomer having two urethane bonds was quantitatively obtained. This product is the monomer M2 of Table I.

This synthesis procedure was repeated using other isocyanates having an ethylenic unsaturation, and other surfactant compounds (alcohols), by adjusting the quantities of

reagents so as to respect the stoichiometry of the reaction. In this way a series of surfactant monomers listed in Table I under references M1 to M88 were obtained.

However, in the case of monomers M51 to M70 which use commercially available ethylenically unsaturated isocyanates, Step 1 of the above-indicated scheme does not exist.

IEM	= isocyanatoethyl methacrylate
IPDI	= isophorone diisocyanate
(C12)2-N	= dilaurylamine radical

Example 2

This example illustrates the preparation of an associative thickening copolymer according to the invention by using the surfactant monomer M2 of Table I.

To this end a pre-emulsion of monomers was first prepared by adding, in the indicated order and under stirring, the following compounds in the weight amounts shown:

Bipermuted water	155.00 g
Na lauryl ether sulfate (powder)	1.75 g
n-Dodecanethiol	0.95 g
Ethyl acrylate	147.50 g
Surfactant monomer M2	25.00 g
Methacrylic acid	100.00 g

In a reactor equipped with a reflux condenser and mechanical stirrer were placed, in the indicated weight amounts,

Bipermuted water	506.00 g
Na lauryl ether sulfate (powder)	2.35 g

The contents of the reactor were brought to 68 °C. 1 gram of ammonium persulfate dissolved in 5 grams of water, and 0.1 gram of sodium metabisulfite dissolved in 5 grams of water were then added. The pre-emulsion of monomers was then continuously introduced for 2 hours and the temperature in the reactor was maintained at 75 °C. The reaction medium was brought to 80 °C for 1 hour, then cooled. In this way an emulsion containing 28.7 % by weight of dry material of associative thickening copolymer W of Table II was obtained. A 2 % aqueous solution of said dry copolymer brought to pH 9 by the addition of ammonia had a viscosity of 120 cP (Brookfield RVT, mobile 2, 100 rpm, 20 °C).

This method of preparation was repeated by using different ethylenically unsaturated surfactant monomers such as those prepared according to Example 1. In this way a series of associative thickening copolymers according to the invention was obtained in the form of an emulsion (references A to AR in Table II).

In this table, and in accordance with the invention, the associative thickening copolymers placed into an aqueous solution containing 2 % dry matter and brought to a pH of 9 by the addition of ammonia and having a temperature of 20 ° all had a Brookfield (type RVT) viscosity at 100 rpm of at most equal to 220 centipoises.

Example 3

The object of this example is to compare associative thickening copolymers, objects of the invention taken from Table II, to commercially available prior-art associative thickening agents.

Among the prior-art associative thickening agents, three of them, reputed to be among the best, were selected for this comparative study.

The first one, called alpha in the text which follows, is PRIMAL RM5, sold by ROHM & HAAS Co.

The second, called beta in the text which follows, is VISCALEX VG2, sold by ALLIED COLLOIDS Co.

The third, called gamma in the following text, is MOWILITH LDM 7000, sold by HOECHST Co.

To carry out this comparison, a series of white gloss aqueous paints was prepared in which only the nature and amount of the associative thickening agents changed.

These paints were formulated from an orientation formula proposed by producers of binding agents to formulators for the binding agent currently used in this type of paint.

The amounts of components of said paints, excluding the thickening agents that are the objects of the comparison, were expressed in grams, whereas the amount of thickening agent was expressed in % of dry polymer relative to the total of each formulation.

The formulations used were compiled in Table III-A and the results in Table III-B.

Commercialisé par la société = Sold by the ... Co. RFA = Federal Republic of Germany.

To use the results of Table III-B, it is desirable to define the methods and/or means employed for obtaining said results.

Viscosity 24 hours

This viscosity was measured in a systematic manner 24 hours after producing each white paint.

The measurement was carried out by means of a Brookfield RVT viscosimeter at 20 °C using a mobile so chosen as to obtain a needle deviation within the graduation range of 15 to 80. The resulting value is representative of the viscosity of said paints in the can (viscosity under low shearing stress).

Apparent viscosity

This measurement was carried out with the aid of a CONTRAVES type RHEOMAT 30 rheometer.

To this end, a small amount of paint was placed in the air gap (50 μm) of an HS 50 mobile, and the shearing stress (τ) as a function of the velocity gradient (D) was recorded. The apparent viscosity is the ratio τ/D for $D = 17700 \text{ sec}^{-1}$.

The shearing stress at 17700 sec^{-1} is representative of the high shearing stresses met with during the use of paints applied by brush or roller. Hence the measured apparent viscosity seems to be a means of observing the potential behavior of the paint when using a brush or roller.

Yield value

This measurement was also carried out with the aid of a CONTRAVES type RHEOMAT 30 rheometer, using a DIN 25 mobile.

To carry out this yield-value measurement, the paint was first subjected to high shearing stress (about 500 sec^{-1}) in order to destructure it. Then the shearing stress as a function of velocity-gradient (D) curve was recorded, said gradient varying from 0 to 5 sec^{-1} . The intersection of the tangent at the low point of the curve and the shearing-stress axis gives the yield value.

Film tension

The film tension after application defines the ability of the paints to level out the thickness irregularities caused by their application on a substrate to be protected. To measure it, a simulation of the irregularities was carried out by depositing on a glass plate five pairs of cords having an initial rectangular cross section, the deposits of each pair being separated by a 2 millimeter interval. The thicknesses of the cords are 0.25 mm, 0.50 mm, 1 mm, 2 mm and 4 mm. The plate was maintained in a horizontal position. After drying, the number of deposit pairs whose cords became joined was noted. Hence the best film tension is 5, i. e. all cord pairs are joined, and the worst was 0, i. e. no pair became joined.

Resistance to running

The resistance to running defines the ability of a paint to resist flowing off after its application to a substrate to be protected.

To measure it, 10 cords 6 mm wide and between 75 and 300 microns thick were deposited on a glass plate by means of a gauge, in increments of 25 microns, the different deposits being separated by an interval of 2 millimeters. The plate is then placed vertically, the thickest deposits being placed at the bottom. After drying, the number of unjoined bands were noted. Hence the best resistance to running is 10 and the worst 0.

The last two measurements, namely film tension and resistance to running, were carried out according to the standard ASTM D 2801-69.

Gloss

Measurement of the gloss, whose technique is well known to persons skilled in the art, was carried out by using an ERICHSEN gloss meter on dry film after 24 hours.

Application

After applying the paint with a brush to a kraft-type substrate, the operator, using his know-how, judged three qualities of application, namely brushability, film tension and covering power, using the following notations:

- Brushability A = excellent
 B = good
 C = average
 D = difficult to apply
 E = very difficult to apply,

the brushability reflecting the more or less agreeable sensation that the user feels during application of the film.

- Film tension
 - A = excellent
 - B = good
 - C = stretches fairly well
 - D = cords a little
 - E = cords a lot

- Covering power
 - A = covers very well
 - B = covers well
 - C = covers fairly well
 - D = covers little
 - E = covers poorly

All the results relating to the above-mentioned tests have been assembled in Table III-B.

Glossary: 1 – Thickening agent (% dry / total formula); 2 – reference, white paint; 3 – Brookfield viscosity 10 rpm; 4 – 24 hours (cP) 100 rpm; 5 – apparent viscosity (mPa.s); 6 - Yield value (Pa); 7 – film tension; 8 – resistance to running; 9 – gloss (%); 10 – 24 hours; 11 – application: brushability; 12 – covering power

From Table III-B it can be noted that the apparent viscosity of the paints thickened by means of the associative copolymers according to the invention is always greater than 200 mPa.s, whereas the apparent viscosity of the paints thickened with the aid of currently sold thickening agents and part of the prior art is always below 200 mPa.s, at constant amounts of thickening agent,

In the case of paint 3-4 (object of the invention) the apparent viscosity is 70 % higher than the best apparent viscosity of prior-art paints.

In the case of paints 3-1 to 3-3, which are prior-art paints, It has been noted that

- for paint 3-1, the viscosity at 24 hours is too low and results in a mediocre resistance to running;
- for paints 3-2 and 3-3 this viscosity at 24 hours is too high and results in a yield value that is too high, which is reflected , on application of the paint, by a bad film tension (cording effect).

For paints 3-4 and 3-5, objects of the invention, decrease of the amount of thickening agent (24 % decrease with respect to the prior art) makes it possible to keep the apparent viscosity at a favorable level, always greater than 200 mPa.s while decreasing the viscosity at 24 hours and the yield value, making it possible without any impairment of the covering power, to improve the film tension and the brushability.

As for paints 3-6 and 3-7 which are also objects of the invention, they offer rheological characteristics and applications that are better than the prior-art characteristics.

Example 4

The object of this example is to compare the associative thickening copolymers, objects of the invention from Table II, to commercially available prior-art associative thickening agents.

Used as prior-art associative thickening agents were the three agents alpha, beta and gamma defined in Example 3.

These paints were formulated from an orientation formula proposed by the manufacturer of binding agents to the formulators for the binding agent used and currently employed in this type of paint.

The amounts of the components of said paints, excluding the thickening agents that are objects of the comparison, were expressed in grams, whereas the amount of thickening agent was expressed as a percentage of dry polymer calculated on the total of each formulation.

The formulations used are listed in Table IV-A and the results in Table IV-B.

The tests listed in Table IV-B were carried out in accordance with the definitions given in Example 3.

All results relating to the aforementioned tests were assembled in Table IV-B.

Glossary: 1 – Thickening agent (% dry / total formula); 2 – reference, white paint; 3 – Brookfield viscosity 10 rpm; 4 – 24 hours (cP) 100 rpm; 5 – apparent viscosity (mPa.s); 6 - Yield value (Pa); 7 – film tension; 8 – resistance to running; 9 – gloss (%); 10 – brushability; 11 – covering power

Table IV-B, in combination with Table III-B, shows the evident superiority of the associative thickening agent H according to the invention. In effect, at identical concentrations of thickening agent, the apparent viscosity of paint 4-4 (object of the invention) is 40 % higher than the best apparent viscosity of the prior-art paintings (4-1 to 4-3).

In the case of paints 4-4 and 4-5 which are the object of the invention, the 26 % decrease in the amount of thickening agent (paint 4-5) leads to a paint whose rheological and use characteristics are always superior to those of the prior-art paints (4-1 to 4-3).

Example 5

The object of this example is to compare the associative thickening copolymers, objects of the invention from Table II, to commercially available associative thickening agents of the prior art.

Used as prior-art associative thickening agents were the three agents alpha, beta and gamma, defined in Example 3.

These paints were formulated from an orientation formula proposed by the manufacturer of binding agents to the formulators for the binding agent used and currently employed in this type of paint.

The amounts of the components of said paints, excluding the thickening agents that are objects of the comparison, were expressed in grams, whereas the amount of thickening agent was expressed as a percentage of dry polymer calculated on the total for each formulation.

The formulations used are listed in Table V-A and the results in Table V-B.

 10 rpm; 4 – 24 hours (cP) 100 rpm; 5 – apparent viscosity (mPa.s); 6 - Yield value (Pa); 7 – film tension;
 8 – resistance to running; 9 – gloss (%); 10 – brushability; 11 – covering power

The tests listed in Table V-B were carried out in accordance with the definitions given in Example 3.

All results relating to the aforementioned tests were assembled in Table V-B.

Table V-B, in conformity with Tables III-B and IV-B, shows that the paint formulated with the associative thickening agent according to the invention (5-6) in an amount of 1,1 % relative to the total weight of the formula has an apparent viscosity that is 30 % better than the prior-art paints (5-1, 5-3 and 5-5) for a same amount of dry thickening agent.

Moreover, in the case of the prior-art paints 5-3 and 5-5 the viscosities at 24 hours (in the can) are too high, producing yield values that are too great and which affect the film tension.

With a view to overcoming this phenomenon, decreasing the amount of thickening agent (references 5-2 and 5-4) produces a reasonable decrease of the viscosity at 24 hours, but a considerable decrease of the apparent viscosity, resulting in an unacceptable reduction of the covering power.

Hence, it appears from Examples 3, 4 and 5 that the acrylic associative thickening agents according to the invention impart to the paints in which they are used rheological and application characteristics which are always better than those of paints thickened by means of commercially available thickening agents reputed to be among the best.

These agents provide the paints not only with a high covering power (high apparent viscosity) but also with an excellent compromise between film tension and resistance to running, which characteristics are naturally antagonistic to one other. Moreover, these agents may be used in lower amounts than the prior art thickening agents, while retaining for the paints containing them better rheological and application characteristics than those of the paints formulated with prior-art thickening agents.

Finally, the thickening agents according to the invention show by the examples that they provide the paints containing them with a regularity of rheological and application characteristics that are not found in the paints formulated with prior-art thickening agents.

Example 6

The object of this example is to illustrate the influence of molecular weight of the associative thickening agent on its ability to be used in a formulation in a gloss aqueous painting.

More particularly, the object of this example is to prove that the molecular weight of said thickening agent must be less than a limit value in order that it retain an ability to be used in said paints, said limit value expressed in Brookfield viscosity being at most equal to 220 centipoises for a 2 % aqueous solution of the dry thickening agents brought to pH 9 by the addition of ammonia at a temperature of 20 °C and for a speed of 100 rpm and a mobile permitting an index deviation of between 15 and 80 at the time of measurement.

In this example, measurement of the RVT Brookfield viscosity relative to the molecular weight of each associative thickening agent tested is carried out not only at a concentration of 2 % but also at a concentration of 1 % of the dry thickening agent, according to the method of measurement described in U. S. Patent 4,514,552, so as to have a common means of measurement making it possible to compare the thickening agents according to the invention and the prior-art thickening agents described in said patent.

To this end, paints were prepared in quantitative and qualitative conformity with test 3-5 of Example 3, i. e. with the same binding agent, which is PRIMAL HG 74 from ROHM & HAAS.

Paints 6-1 and 6-3 contained prior-art thickening agents, and paints 6-5 and 6-6 contained thickening agents according to the invention, said thickening agents having been used in an amount of 0.62 % of dry product relative to the total of the formula.

Paints 6-2 and 6-4 contained prior-art thickening agents, but in lower amounts.

The results relating to the aforementioned paints and to the tests carried out on said paints, as they have been defined in Example 3, are assembled in Table VI.

alc allyl. = alcool allylique

MAEG = méthacrylate d'éthylène glycol

TDI = toluène diisocyanate

C12 23 OE = lauryl poly(éthylèneoxy)22-éthanol

Glossary: 1 - reference, white paint; 2 - reference of polymer; 3 - prior art; 4 - nature of polymer; 5 - allyl alcohol; 6 - viscosity, 2 %; 10 rpm; 7 - % dry thickening agent / total; 8 - Brookfield viscosity; 9 - 24 hours; 10 - apparent viscosity; 11 - yield value (Pa); 12 - film tension; 13 - resistance to running; 15 - gloss; 15 - brushability; 16 - covering power.

MAEG = ethylene glycol methacrylate; TDI = toluene isocyanate; C12 23 OE = lauryl poly(ethyleneoxy)₂₂ ethanol

From this table the following observations can be made:

Paints 6-1 and 6-3 (relating to the prior art) have very high viscosities at 24 hours, which produce unacceptable yield values that are reflected by a very poor film tension (highly marked cording), even though the apparent viscosity of said paints is not affected by the thickening agents used.

The formulations of paints 6-5 and 6-6 (relating to the invention), which have apparent viscosities close to those measured in the case of the prior art, differ from the prior art by much lower 24-hour viscosities and yield values, which greatly favor the film tension, an essential criterion for the application of said paints.

The formulations of 6-2 (to be compared to 6-1) and 6-4 (to be compared to 6-3) which relate to the prior art, were the object of a decrease of the amount of thickening agent with a view to reducing the 24-hour viscosities and the excessive yield values in order to improve the film tension. However, from the results it appears that the decrease of the amount of thickening agent causes a redhibitory drop of the apparent viscosity and hence of the covering power.

Finally, as can be seen from U. S. Patent 4,514,552, the thickening agents described therein have a viscosity, in aqueous solution at a concentration of 1 % at 10 rpm, that is greater than or equal to 178 centipoises, while the viscosity of solutions of the copolymers according to the invention under the same conditions is at the most 40 centipoises, as indicated in Table VI.

Hence it is confirmed that the average molecular weights of the thickening agents must not exceed a limit value which is represented by the viscosity measured according to the aforementioned conditions at an amount of 2% of said agent, which is 220 centipoises at 100 rpm, in order that the thickening agents, which are objects of the invention, simultaneously impart to the paints in which they are used a good rheological

compromise at high and low shearing stresses, reflected simultaneously by a good covering power and excellent film tension, criteria which are never achieved by the paints formulated by using the type of thickening agents belonging to the prior art.

Example 7

The object of this example is to confirm the influence of the molecular weight of the thickening agent on its ability to be used in gloss aqueous paints based no longer on PRIMAL HG 74 as in Example 6, but on NEOCRYL XK 76 sold by POLYVINYL CHEMIE.

The paints tested were prepared in quantitative and qualitative conformity with test 5-1 of Example 5, except for the type of thickening agent and the amount in which it was used in said paints.

Paints 7-1 and 7-3 (of the prior art) and 7-5 and 7-6 (objects of the invention) used different thickening agents but in the same amount.

Paints 7-2 and 7-4 (of the prior art) used different thickening agents in lower amounts than for the other paints.

The results relating to the aforementioned paints and to the tests carried out on said paints as they have been defined in Example 3 are assembled in Table VII.

TABLE VII

Glossary: 1 - reference, white paint; 2 - reference of ... polymer; 3 - prior art; 4 - nature of polymer; 5 - allyl alcohol; 6 - viscosity, 2 %; 10 rpm; 7 - % dry / total; 8 - Brookfield viscosity; 9 - 24 hours; 10 - apparent viscosity; 11 - yield value (Pa); 12 - film tension; 13 - resistance to running; 14 - gloss; 15 - brushability; 16 - covering power.

MAEG = ethylene glycol methacrylate; TDI = toluene isocyanate; C12 23 OE = lauryl poly(ethyleneoxy)₂₂ ethanol

This table leads to the following conclusions. In the same way as in Example 6, the thickening agents used in paints 7-1 and 7-3 impart to them a very high viscosity at 24 hours and very high yield value, reflected by a very poor film tension (highly marked cording), even though the apparent viscosity of said formulations is not affected by the thickening agents used.

These same thickening agents used in smaller amounts (7-2 and 7-4) lead to acceptable viscosities at 24 hours and acceptable yield values, improving the film tension but destroying the apparent viscosity and hence the covering power at the application level.

The thickening agents objects of the invention responding to the selective limit of molecular weights according to the invention, impart to the paint formulation in which they are used an excellent rheological compromise at high and low shearing stresses, reflected simultaneously by a good covering power and good film tension, as has already been noted in Example 6.

Example 8

The object of this example is to show the superiority of the associative thickening agents according to the invention over the prior-art thickening agents from the point of view of their compatibility with colored inorganic or organic pigments present in the form of a pigment paste.

By compatibility with pigments, the sum total of the following observed effects is meant:

- absence of a substantial increase in the viscosity of the paint after addition of the pigment paste;
- absence of deterioration of the film tension of the colored paint,
- absence of pigment flotation, reflected by their rising to the surface of the paint can.

Understood by "pigment paste" is any concentrated suspension of inorganic or organic pigments introduced into a white paint in order to color it.

The pigment pastes used are described in Table VIII-A, and are currently used in the paint profession.

Thus, the white paints having at least one of the following disadvantages:

- too high viscosity in the can (i. e. Brookfield 24-hour viscosity) and too high yield value (resulting in a poor film tension: cases of tests 3-2, 5-3, 6-1, 6-3, 7-1 and 7-3).
- too low apparent viscosity (little covering power: case of tests 3-2, 4-2, 4-3, 5-2, 5-4, 6-2, 6-4, 7-2 and 7-4).

have been eliminated from the coloring tests.

By contrast, white paints showing a good rheological compromise at high and low shearing stresses (reflected by a good covering power and good film tension) were subjected to the coloring tests.

To this end, paints meeting the aforementioned selection criteria, chosen from Examples 3 to 5, were colored by the addition, under mechanical stirring, of 5 parts by weight of pigment paste per 100 parts by weight of white paint, this quantity having been chosen arbitrarily.

TABLE VIII-A
References of pigment pastes

Pigment paste No.	Type	Commercial reference	Producer
1	Yellow iron oxide	Telochrome TC 21 EJ 603	Telosud
2	Red iron oxide	Telochrome TC 21 ER 317	Telosud
3	Chromium yellow	Telochrome TC 21 EJ 655	Telosud
4	Phthalocyanine blue	Luconyl 6900	BASF
5	Phthalocyanine green	Green 8J	Astra
6	Dinitraniline red	Red 2 J	Astra
7	Carbon black	Black V	Astra
8	Hansa yellow	Yellow 10J	Astra

The Brookfield viscosity at 24 hours of the colored paints was systematically measured in the can in order to note any appreciable increase in viscosity which would be injurious to the quality of the paint and which would be reflected by incompatibility between the thickening agent used and the pigment paste.

All results relating to this study are assembled in Table VIII-B and relate to the Brookfield 24-hour viscosity, to the possible floating of the pigments and to the quality of the color developed.

Glossary: 1 - Binder; 2 - Thickening agent; 3 - Amount (a); 4 - Reference, white paint; 5 - Brookfield viscosity (cP) 10 rpm; 6 - at 24 hours 100 rpm; 7 - white paint; 8 - Paste No.; 9 - maximum increase in viscosity, 10 rpm; 10 - average variation of viscosity, 10 rpm

(a) % dry / total formula

‡ pigment flotation

\$ excellent color development

From this table, the following noticeable observations can be made:

- In the case of paints colored by means of pigment paste No. 7, the results are mediocre, except in one case (white paint 4-4, colored with pigment paste No. 7);
- With the exception of the paints formulated by means of pigment paste No. 7, the colored paints thickened by means of the thickening agent according to the invention show
 - very few cases of pigment flotation,
 - a color development that is at least always equivalent and often better than that obtained with the paints containing prior-art thickening agents, at identical binders and pigment pastes,
 - finally and especially a remarkable absence of redhibitory increase of the Brookfield 24-hour viscosity.

To illustrate the remarkable absence of redhibitory increase of this viscosity, Table VIII-B shows in the last two lines

- the maximum increase of Brookfield viscosity at 10 rpm in relation to the white paint,
- the average algebraic value of the variation of said viscosity.

The calculations were made by excluding the results obtained with pigment paste No. 7 which were found to be generally very mediocre whichever thickening agent was used, as has already been stated.

Thus, the maximum increases and the average values of the variation of viscosity show that only the colored paints containing the thickening agents of the invention are not subject to a redhibitory viscosity increase relative to the original white paint.

Claims

1. Associative thickening copolymer water-soluble in a neutral or alkaline medium, for charged and/or pigmented, white or colored aqueous compositions, composed

a) of at least one ethylenically unsaturated monomer having at least one carboxylic function,

b) of at least one other ethylenically unsaturated monomer devoid of carboxylic function.

c) of at least one surfactant monomer having at least one urethane function resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound, having a hydroxyl function that is reactive towards the –NCO group,

characterized in that said copolymer belongs to the group consisting of those which, by definition, when placed in an aqueous solution containing 2 % by weight of dry matter and brought to pH 9 by the addition of ammonia, at a temperature of 20 °C, have a Brookfield viscosity at 100 rpm of at most equal to 220 centipoises.

2. Copolymer according to Claim 1, characterized in that the ethylenic monomer (a) having at least one carboxyl function is selected from the group comprising the monoacids acrylic acid, methacrylic acid, crotonic acid, cinnamic acid, the diacids itaconic acid, fumaric acid, maleic acid, citraconic acid, maleic anhydride and the C₁ to C₄ half esters of diacids.

3. Copolymer according to Claims 1 or 2, characterized in that the carboxylated ethylenic monomer is preferably acrylic acid, methacrylic acid or itaconic acid.

4. Copolymer according to any one of Claims 1 to 3, characterized in that the ethylenically unsaturated monomer (b) devoid of carboxyl function is selected from the group comprising methyl, ethyl, butyl, 2-ethylhexyl, lauryl acrylates or methacrylates, ethylene glycol, propylene glycol, polyethylene glycol and polypropylene glycol acrylates and methacrylates and the corresponding phosphates and sulfates,

acrylonitrile, acrylamide, N-methylolacrylamide, dimethylaminoethyl acrylates and methacrylates, allyl alcohol, vinyl acetate, acrylamidomethyl-propanesulfonic acid, styrene and methylstyrene.

5. Copolymer according to any one of Claims 1 to 4, characterized in that the ethylenically unsaturated monomer (b) is preferably selected from among the C₁ to C₄ acrylates and methacrylates.

6. Copolymer according to any one of Claims 1 to 5, characterized in that the ethylenically unsaturated isocyanate involved in the make-up of the surfactant monomer (c) results from the reaction of a diisocyanate with an ethylenic compound having a function that is reactive towards the –NCO group.

7. Copolymer according to Claim 6, characterized in that the diisocyanate is selected from the group comprising 1,4-tetramethylene diisocyanate, 1,6-hexamethylene diisocyanate, 2,2,4-trimethyl-1,6-diisocyanatohexane, 1,10-decamethylene diisocyanate, 4,4-methylene-bis(isocyanatocyclohexane), 1,4-cyclohexylene diisocyanate, 1-isocyanato 3-isocyanatomethyl-3,5,5-trimethylcyclohexane, m- and p-phenylene diisocyanate, 2,4- and 2,6-toluene diisocyanate, xylene diisocyanate, 4-chloro-1,3-phenylene diisocyanate, 4,4'-methylene diphenylisocyanate, 1.5-naphthalene diisocyanate and tetrahydronaphthylene diisocyanate.

8. Copolymer according to Claim 6, characterized in that the ethylenic compound having a function reactive towards the –NCO group is selected from the group comprising the ethylene glycol, propylene glycol, polyethylene glycol and polypropylene glycol acrylates and methacrylates, allyl alcohol, allylamine, methallylamine and o-allylphenol.

9. Copolymer according to any one of Claims 1 to 8, characterized in that the

surfactant compound involved in the make-up of the surfactant monomer (c) has the formula

wherein

- the term $(O - R_2)$ is ethylene oxide, propylene oxide, butylene oxide or a combination of at least two of these oxygenated groups;
- n, which represents the average number of terms present in said surfactant compound, has a value of between 5 and 150;
- the term R_1 , comprising 1 to 32 carbon atoms, is selected from the group consisting of hydrocarbon- and/or amine-containing chemical structures such as aliphatic or cycloaliphatic alkyls, substituted or unsubstituted aryls, polyaryls, secondary amines of formula $(R_3)(R_4)N$ - wherein R_3 and R_4 are hydrocarbon groups having 1 to 20 carbon atoms.

10. Copolymer according to Claim 9, characterized in that the term R_1 is preferably selected from among C_{12} to C_{30} hydrocarbon chains, the $-O-R_2$ term from among ethylene and/or propylene oxides, and n in the range of 15 to 50.

11. Copolymer according to one of Claims 9 or 10, characterized in that the surfactant compound is preferably selected from the group comprising ethoxylated dilaurylamines, ethoxylated octyl- and nonylphenols, oxyethylated lauryl alcohol, stearyl alcohol, cetyl alcohol, ethoxylated di- and tristerylphenols, taken alone or in a mixture.

12. Copolymer according to any one of Claims 1 to 11, characterized in that it contains, expressed as a percentage by weight,

- a) from 15 to 75 %, preferably 30 to 45 % by weight of ethylenically unsaturated monomer(s) having at least one carboxylic function;
- b) from 25 to 70 %, preferably 45 to 60 % of other ethylenically unsaturated monomer(s) devoid of carboxylic function,

- c) from 0.5 to 35 %, preferably 4 to 15 % of surfactant monomer(s) having at least one urethane function resulting from the reaction of an ethylenically unsaturated isocyanate with a surfactant compound having a hydroxyl function reactive towards the –NCO group.

13. Copolymer according to any one of Claims 1 to 12, characterized in that it is at least partially neutralized.

14. Copolymer according to Claim 13, characterized in that the neutralization agent is preferably lithium hydroxide, sodium hydroxide, potassium hydroxide, ammonium hydroxide, calcium hydroxide, magnesium hydroxide or an amine, taken alone or in combination.

15. Charged and/or pigmented aqueous compositions, characterized in that they contain the copolymer defined in Claims 1 to 14.

16. Charged and/or pigmented aqueous compositions according to Claim 15, characterized in that, white or colored, they contain as principal components an aqueous phase, charges and/or pigments, a natural or synthetic binder, the associative thickening copolymer according to Claims 1 to 14, and possibly, as secondary components, a dispersant, additives as diverse as coalescence agents, biocides, surface-active agents and antifoaming agents.

17. Aqueous compositions according to one or the other of Claims 15 or 16, characterized in that the thickening copolymer is introduced therein in an amount of 0.1 % to 10 %, preferably 0.1 % to 5 %, and very preferably 0.4 % to 1.5 % by dry weight relative to the total weight of said compositions.

18. Application of the thickening copolymer according to any one of Claims 1 to 17 to aqueous coating compositions, aqueous paints, coating slips, printing pastes, leather finishing products, cosmetic compositions, detergents and drilling fluids.
